Lidar wall tracking-straight line

Lidar wall tracking-straight line

Hardware connection
Control principle
Main code

Program flow chart

Experimental phenomenon

The tutorial mainly demonstrates the function of the balance car combined with the Tmini-Plus radar to follow the wall in a straight line.

The tutorial only introduces the standard library project code

Hardware connection

Since we have configured a special connection line, you only need to install it to the corresponding interface.

Peripherals	Development Board
Tmini-Plus radar: VCC	5V
Tmini-Plus radar: TXD	PC10
Tmini-Plus radar: RXD	PC11
Tmini-Plus radar: GND	GND

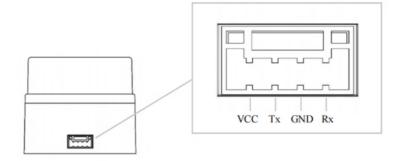

Control principle

The program analyzes the radar data, and sets the distance from the wall and the distance to be maintained for patrolling the wall according to the distance collected by the program initialization (radar 72° distance). The 0° distance determines whether there is an obstacle in front.

The right side of the radar needs to be close to the wall, and the angle of distance measurement is $72\,^\circ$

• Tmini-Plus radar

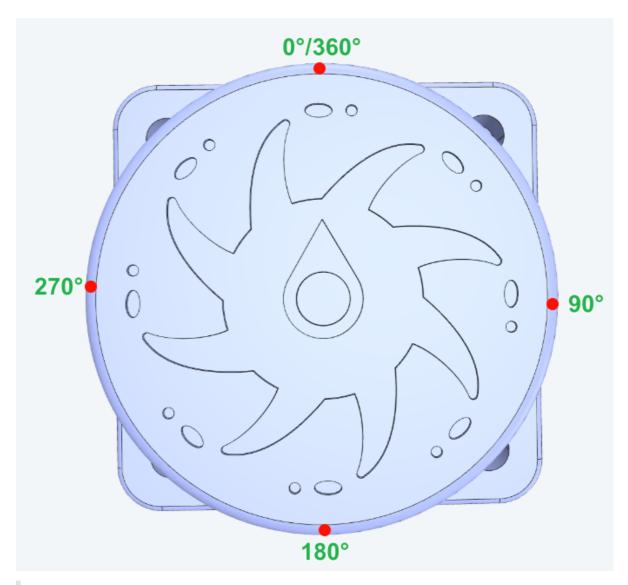

Product name	Tmini-Plus radar
Scanning frequency	6-12Hz
Sampling frequency	4000 times/s
Measuring radius	Black object: 12m
Minimum measuring distance	0.05m
Distance measurement principle	TOF distance measurement
Scanning angle	360°
Communication interface	Standard asynchronous serial port (UART) 1. Baud rate: 230400 2. Data bits: 8 3. Check bit: None 4. Stop bit: 1
ROS support	ROS1/ROS2
Windows support	Host computer

Radar angle distribution

The arrow in the center of the radar points to $0^{\circ}/360^{\circ}$, and the angle increases clockwise.

Communication protocol

For detailed information, please refer to the "T_Mini_Plus Manual"

Main code

The tutorial mainly explains the code for the radar to follow the wall in a straight line. For detailed code, please refer to the corresponding project file.

LiDar_Straight

The radar 0° distance data is used to determine whether there is an obstacle in front of the balance car, and the radar 72° distance is used to determine the distance between the balance car and the wall, and PID processing is performed based on this distance.

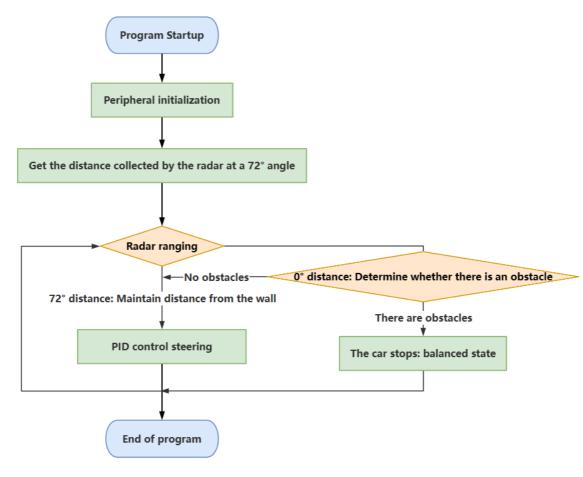

```
if(get_timedis<GET_LidarDIS_Time)</pre>
            if(Tminidis[Lidar_Angle]==0 || Tminidis[Lidar_Angle]>400) continue;
// Discard data with a size of 0 or greater than 400 mm
            get_timedis ++;
            target_distance = Tminidis[Lidar_Angle];// Dynamically obtain the
target angle
            Limit_distance=target_distance+200;// 200mm larger than the target
distance, mainly to avoid the disappearance of the reference object causing the
car to turn quickly
            if(get_timedis == (GET_LidarDIS_Time-1))
            {
                g_1idar_go_flag = 1;
                get_timedis = GET_LidarDIS_Time;
            }
        }
         if(Tminidis[Lidar_Angle]<(Limit_distance))// Limit the detection range</pre>
of the radar
        {
             current_distance=Tminidis[Lidar_Angle];// Determine distance
        }
    }
    if(get_timedis<GET_LidarDIS_Time) // When the distance is not determined, do
nothing
    {
        return;
    }
    if(Tminidis[0]>0 && Tminidis[0]<400)// Stop due to an obstacle ahead
        Move_X = 0;
        Move_Z = 0;
        return;
    }
    Set_track_speed();
    Move_Z = Distance_Adjust_PID(current_distance, target_distance);
}
```

Distance_Adjust_PID

PID processing is performed based on the distance between the radar and the wall. If the balancing car does not patrol the wall in a straight line effectively, modify the PID parameters of the app_lidar_car.c file. It is not recommended to modify the PID parameters of the pid_control.c file (the PID parameters of the pid_control.c file are subject to the parameters finally confirmed in the balancing car parameter adjustment tutorial).

Program flow chart

Briefly introduce the process of function implementation:

Experimental phenomenon

Software code

The Balance_Radar_Line.hex file generated by the project compilation is located in the OBJ folder of the Balance_Radar_Line project. Find the Balance_Radar_Line.hex file corresponding to the project and use the FlyMcu software to download the program into the development board.

```
Product supporting materials source code path: Attachment \rightarrow Source code summary \rightarrow 5.Balanced_Car_Extended \rightarrow 16.Balance_Radar_Line
```

After the program is started, press KEY1 according to the OLED prompt to start the radar of the balance car to follow the wall in a straight line:

OLED displays wait get dis!: The balance car will take 1 second to obtain the distance of the wall that the radar needs to patrol (the right side of the radar needs to be close to the wall, and the source of the patrol distance is the 72° position of the radar); OLED displays start track!: Start the radar wall-following mode.

If an obstacle is encountered during the patrol process, the wall-following mode will be stopped; remove the obstacle to resume the wall-following mode.

The program has voltage detection. If the voltage is less than 9.6V, a low voltage alarm is triggered and the buzzer will sound.

Common situations for triggering voltage alarms:

- 1. The power switch of the development board is not turned on, and only the Type-C data cable is connected for power supply
- 2. The battery pack voltage is lower than 9.6V and needs to be charged in time
